

Assignment 2 – Part A

Your task is to write a program “analysis_pcap_tcp” that analyzes a Wireshark/TCPdump trace to characterize the TCP flows in the trace. A TCP flow starts with a TCP “SYN” and ends at a TCP “FIN”

Building:

```
gcc -lm analysis_pcap_tcp.c -o analysis_pcap_tcp
```

Only external library used is the math library (-lm). All other APIs are intrinsic to gcc.

Running:

```
./analysis_pcap_tcp
```

Note – The program will read **assignment2.pcap** as default pcap file from the current location. The file must be present there.

Output:

For the given pcap file the output is as follows

```
neha:Part A$ ./a.out
```

```
Part A
```

```
1. Total Number of TCP Flows initiated by the Sender - 3
```

```
2 (a) First 2 transactions per Flow
```

| Flow | Ports | Seq_Num | Ack_Num | Dest_Seq_Num | Dest_Ack_Num | Recv_Window | Length |
|------|-----------|------------|------------|--------------|--------------|-------------|--------|
| 1 | 43498->80 | 705669103 | 1921750144 | 1921750144 | 705669127 | 49152 | 90 |
| 1 | 43498->80 | 705669127 | 1921750144 | 1921750144 | 705670575 | 49152 | 1514 |
| 2 | 43500->80 | 3636173852 | 2335809728 | 2335809728 | 3636173876 | 49152 | 90 |
| 2 | 43500->80 | 3636173876 | 2335809728 | 2335809728 | 3636175324 | 49152 | 1514 |
| 3 | 43502->80 | 2558634630 | 3429921723 | 3429921723 | 2558634654 | 49152 | 90 |
| 3 | 43502->80 | 2558634654 | 3429921723 | 3429921723 | 2558636102 | 49152 | 1514 |

```
2 (b) Throughput
```

| Flow | Ports | Sent (B) | Time (s) | Throughput (Mbps) |
|------|-----------|----------|----------|-------------------|
| 1 | 43498->80 | 10552802 | 2.010401 | 41.992824 |
| 2 | 43500->80 | 10552802 | 8.320370 | 10.146474 |
| 3 | 43502->80 | 1096664 | 0.740275 | 11.851423 |

```
2 (c) Loss Rate
```

| Flow | Ports | Packets Sent | Packets Lost | Loss Rate |
|------|-----------|--------------|--------------|------------|
| 1 | 43498->80 | 6976 | 3 | 0.00043005 |
| 2 | 43500->80 | 7067 | 94 | 0.01330126 |
| 3 | 43502->80 | 728 | 0 | 0.00000000 |

```
2 (d) Average RTT
```

| Flow | Ports | Average RTT | Theoretical Throughput | Empirical Throughput |
|------|-----------|-------------|------------------------|----------------------|
| 1 | 43498->80 | 0.073518 | 6.317771 | 41.992824 |
| 2 | 43500->80 | 0.088418 | 0.944563 | 10.146474 |
| 3 | 43502->80 | 0.073290 | inf | 11.851423 |

```
neha:Part A$
```

EXPLANATIONS

2(a). The program outputs the first two transactions for each flow after the TCP connection is setup (handshake is complete). The columns in the output represent the Flow number, Ports (Sender->Receiver), Sequence Number of the sent packet, Acknowledgment Number of the sent packet, Sequence Number of the received acknowledgment, Acknowledgment Number of the received acknowledgment, Receive Window Size and Total Length of packet in bytes respectively.

2(b). Here I calculate the empirical throughput of each flow. It is calculated as the total number of bits successfully sent over the total time taken to sent the packet. The output is in Megabits per second (Mbps)

2(c). Here I calculate the loss rate for each flow. It is calculated as the total number of packets lost during transmission compared to the total number of packets sent.

2(d). Here I calculate the average RTT of each flow. An RTT of a packet is considered as the time duration between the sent packet and the received acknowledgment of the packet. I am ignoring the time for any packet which were lost during transmission.

Here I also print the theoretical throughput of each flow and compare it with the empirical throughput as calculated by the program. As seen there is a huge difference between the two throughputs. The reasons for this difference could be anything like network overhead, external performance limiters, and network configuration problems. When assessing the performance of networks, there is always a difference between theoretical throughput and “real-world” throughput. There is no option for the difference between theoretical and practical performance being “negligible”!
